

## Evolutionary Ecology of *Crassostrea virginica* and its Parasites

### *Perkinsus marinus*

- ❖ Endemic species, agent of "dermo disease" in oysters
- ❖ Directly transmissible among *Crassostrea virginica*

### *Haplosporidium nelsoni*

- ❖ Introduced pathogen (Bureson et al. 2000), agent of "MSX disease"
- ❖ Complex life cycle likely requiring intermediate host(s) for transmission

## Oyster and Parasite Distribution, Present

— *C. virginica*  
— *P. marinus*  
— *H. nelsoni*

## Oyster and Parasite Distribution, 1959

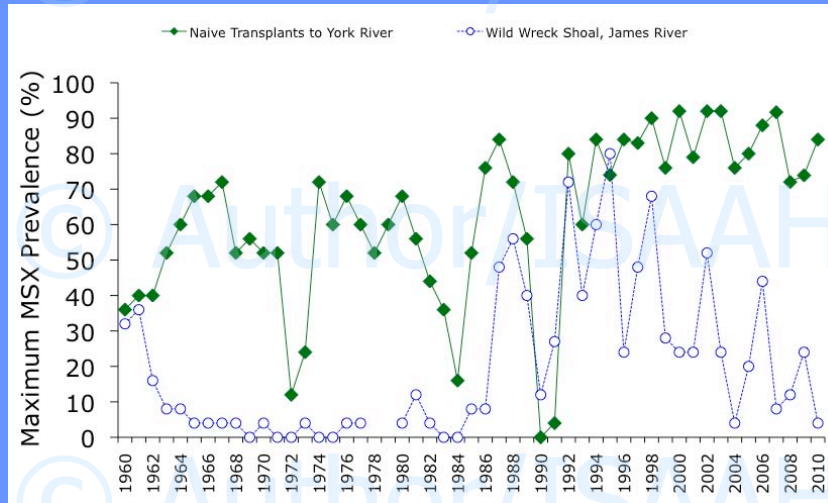

— *C. virginica*  
— *P. marinus*  
★ *H. nelsoni*

- ❖ MSX introduction brought sharp changes to the pre-1959 system
- ❖ Very high host mortality
- ❖ Sudden competition between two parasites, one (MSX) introduced and very virulent

## Resistance to MSX

*Haplosporidium nelsoni* in James River Oysters vs. Naïve Sentinels

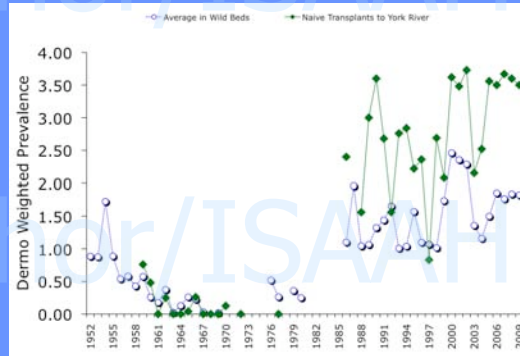

## Resistance to *Perkinsus marinus*

*Perkinsus marinus* in Wild York/Mobjack Oysters v. Naïve Sentinels

## Intensification of *Perkinsus marinus*, 1980s

- ❖ *P. marinus* levels in wild oysters are much higher now than in early years
  - Particularly *body burdens*
  - Prevalence then and now approached 100%
- ❖ Intense disease and mortality develop much more rapidly than before the arrival of MSX
- ❖ An increase in virulence in the mid-1980s

A Question:

## Is This Not Adaptive?

- ❖ *Perkinsus marinus* is transmitted primarily through the deaths of infected oysters (Ragone Calvo et al. 2003)—before MSX this began 2-3 years after initial exposure (Andrews 1956)
- ❖ Parasite body burdens were relatively low in the 1950s (Andrews 1980), but still ensured effective transmission among oysters at a time when oysters were particularly abundant

Is an increase in body burdens (higher weighted prevalences since the 1980s) and generally more rapid rate of infection development convincing evidence of a virulence increase?

Or can this still be explained by simple numerical abundance?

Not a definitive sign that *P. marinus* has fundamentally changed or evolved

## Where are the Schizonts?

- Contemporary histology suggests far more binary division than schizogony

- Is binary division by cells that never grow to large size adaptive?
- Is *P. marinus* population growth rate increased by having a high proportion of cells going through binary division, rather than a small subset going through schizogony?
- Anecdotal evidence: more binary division in faster-growing cultures—suggests link between histological presentation (i.e., phenotype) and virulence (La Peyre 1996)

## Perkinsus marinus Conclusions

- ❖ Fundamental *phenotypic* change in *P. marinus* between 1985 and 1986
  - General abandonment of schizogony in favor of binary division by small cells
- ❖ Simultaneous increase in virulence
- ❖ Hypothesize 1<sup>st</sup> that the virulence increase is associated with the change in *P. marinus* expression
- ❖ Hypothesize 2<sup>nd</sup> that this reflects selection for increased virulence induced by *H. nelsoni*, at least indirectly

## Summary

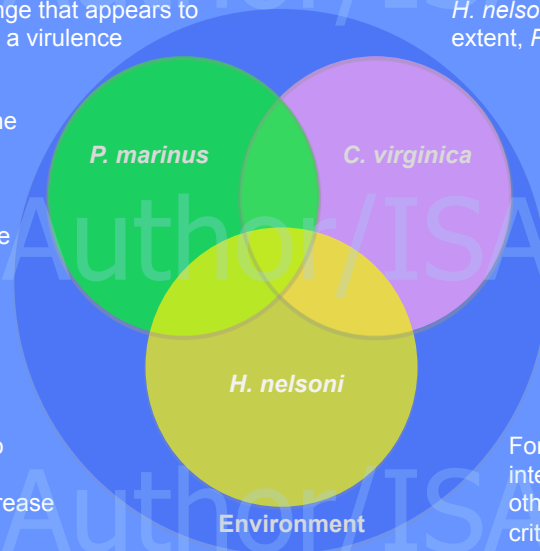

In *P. marinus*, a fundamental phenotypic change that appears to correspond with a virulence increase

What induced the change?

Can we find genetic evidence for it?

In *H. nelsoni*, no evidence for an increase or decrease in virulence

In oysters: resistance to *H. nelsoni*, and to a lesser extent, *P. marinus*

For *H. nelsoni*, interactions with other hosts may be critical
